Multicolored Temperley-Lieb lattice models.
The ground state.

Abstract

Using the inversion relation method, we calculate the ground state energy for the lattice integrable models, based on baxterization of multicolored generalization of Temperley-Lieb algebras. The simplest vertex and IRF models are analyzed and found to have a mass gap.

1 Introduction

Looking for new solutions of Yang-Baxter equation is an interesting and important problem in exactly solvable statistical models. Some time ago set of new solutions of Yang-Baxter equations were obtained [1] by "baxterization" of multicolored generalization of Temperley-Lieb (TL) algebras - Fuss-Catalan algebras – discovered by Bisch and Jones [2]. These solutions are really new and are not equivalent to a fusion of known models. In [1] these solutions were formulated in terms of generators of this new algebra, and in principle the Boltzmann weights may be interpreted both as a vertex model, or as an interaction round the face (IRF) models defined on a tensor product of admissibility graphs corresponding to different colors of the TL algebra. Physical interpretation of these new integrable models may be different. In addition to construction of new integrable vertex and IRF models, an obvious possible realization of these new solutions is multicolored generalization of dense loop models [1], polymers and other subjects of exactly solvable statistical models (for a review see e.g. [3]). Another new integrable model of the same class was obtained as integrable solution for Lorentz lattice gases [4], [5] and dimerised coupled spin-1/2 chain [6].

In spite of traditional form of the R-matrix, it turns out that the usual algebraic Bethe ansatz solution, at least in its naive and straightforward version, reveals some technical problems. One of the possible reasons for that might be a non trivial structure of pseudo vacuum, which is hard to guess in a way effective for realization of algebraic Bethe ansatz program. The alternative method for investigation of physical properties of integrable models, such as ground state energy, its free

energy, spectrum and correlation functions is the method of inversion relations. It doesn't require explicit form of BA equations or transfer matrix eigenvalues, valid in the thermodynamic limit. It was taken up by Baxter (see, e.g. [7], [8]) and further developed by others (see e.g. [9], [10]). It exploits functional inversion relations for the transfer matrix in the ground state, and transfer matrix analytical properties, in order to calculate ground state energy and low lying excitations spectrum [10]. Assumptions on the transfer matrix eigenvalue analytical properties usually should be confirmed numerically. The advantage of this method is that it doesn't require knowledge of Bethe ansatz equations and eigenvalues of transfer matrix explicitly, but gives a possibility to find basic physical quantities of the model quite easily.

Plan of the paper is the following. We start Sect.2 with description of the Boltzmann weights of the models in terms of multicolored TL generators and their algebraic relations. We analyze possible physical regimes, where Boltzmann weights are real and positive, and discuss possible vertex and IRF interpretation of the models. Some interesting factorization property of admissibility graph for IRF models is pointed out. In Sect.3 we derive functional inversion relations for the transfer matrices of two colored vertex model and for the partition function of two colored IRF model. We solve them analytically as a product of analytical non zero function, and a function with poles or zeros. Excited states are discussed and found to lead to a mass gap. In Sect.4 generalization of inversion relations for multicolored models is discussed. We conclude by Sect.5 with a discussion of the obtained results.

2 Colored TL lattice models.

In this section we recall the results of [1] and demonstrate them for few examples of two, three and four colored models. For details of Fuss-Catalan algebras and their representations we refer a reader to [2] and [1]. We also discuss vertex and IRF representations of baxterized Fuss-Catalan models and find their possible physical regimes.

2.1 Solutions of Yang-Baxter equation with Fuss-Catalan symmetry.

New class of TL like algebras found by Bisch and Jones [2] can be considered as a kind of quotient of tensor product of few TL algebras. Generators of these algebras may be formulated in terms of TL generators defined on a lattice. The relations on generators depend on the parity of the site i where the operator acts. The main commutation relations [2] are the following.

$$U_i^{(m)}U_i^{(p)} = U_i^{(p)}U_i^{(m)} = \rho_i(\min(m,p))U_i^{(\max(m,p))} \tag{1}$$

where

$$\rho_i(p) = \begin{cases} \alpha_1\alpha_2...\alpha_p & i\ -\ even \\ \alpha_k\alpha_{k-1}...\alpha_{k+1-p} & i\ -\ odd \end{cases} \tag{2}$$

Here k is the number of colors is, and in the standard strings pictorial interpretation of the operators $U^{(m)}$ weight α_m is attached to each loop of color m. Locality of operators U expressed as

$$U_i^{(m)}U_j^{(p)} = U_j^{(p)}U_i^{(m)} \tag{3}$$

when $|i-j|>1$, or when $|i-j|=1$ and $m+p\leq k$. Non commuting operators satisfy cubic relations

$$U_i^{(m)}U_{i\pm1}^{(p)}U_i^{(q)} = \rho_i(k-p)\begin{cases} U_i^{(m)}U_{i\pm1}^{(k-q)} & m\geq q \\ U_{i\pm1}^{(k-m)}U_i^{(q)} & m\leq q \end{cases} \tag{4}$$

These are basic relations of the Fuss-Catalan algebra $FC_{k(N+1)}(\alpha_1, \alpha_2, ...\alpha_k)$ which describes coils of $k(N+1)$ strings of k colors. Boundary conditions are fixed by requirement that both on the top and on the bottom strings end up by the same pattern $a_1 a_2 ... a_k a_k a_{k-1} ... a_2 a_1 a_1 ...$. Pictorial interpretation of the commutation relations written above one can find in [1]. Lets note that not all of the relations written above are independent (for details see [2], [1]). There are some consequences of these relations necessary, in particular, if one wishes to check validity of Yang-Baxter equations for the baxterization solutions, but we will not stop on these technical details here.

In [1] baxterization of this algebra was successfully done. Namely, all possible solutions of the Yang-Baxter equation

$$W_i(x)W_{i+1}(xy)W_i(y) = W_{i+1}(y)W_i(xy)W_{i+1}(x) \tag{5}$$

were found in the form

$$W_i(x) = 1_i + \sum_{m=1}^{k} a_m(x) U_i^{(m)} \tag{6}$$

satisfying

$$W_i(1) = 1_i \tag{7}$$

in the class of rational polynomial functions $a_m(x)$. It was done by substitution of (6) into (5), which, using the Fuss-Catalan algebra, leads to a complicated system of functional equations on the coefficients $a_m(x)$. General solution of this system of functional equations was found to be:

$$\begin{aligned} a_m(x) &= \frac{1}{\rho_m} x^{r_1 + r_2 + ... + r_{m-1}} (x^{r_m} - 1), \quad m = 1, 2, ...k-1. && (8) \\ a_k(x) &= \frac{\rho_1}{\rho_{k-1}} x^{r_1 + r_2 + ... + r_{k-2} + 1} \frac{x^{r_{k-1}} - 1}{\mu - x}, && (9) \end{aligned}$$

where $\rho_m \equiv \rho_i(m)$ are defined in (2), $r_m = \{\pm 1\}$, and r_m and other parameters entering the last equations, are restricted and defined by the following set of relations: $r_1 = r_{k-1} = 1$ and either $r_{q-1} = r_q = r_{k-q} = r_{k-q+1}$, or $r_{q-1} = -r_q = -r_{k-q} = r_{k-q+1}$, and

$$\mu^{(r_{q-1} + r_q)/2} = \alpha_q^2, \mu = \alpha_1^2 - 1, \alpha_q = \alpha_{k+1-q} \tag{10}$$

for any $q = 2, ..., k-1$. In [1] the special solution with $r_1 = r_2 = ... = r_{k-1} = 1$ was called fundamental. With this set of r_q one has $\mu = \alpha_1^2 - 1 = \alpha_2^2 = ... = \alpha_{k-1}^2$. These equations were solved in the assumption that all α's are positive. We will relax this condition and permit two possible branches of the square root when solving (10) with respect to α_q. For real α_q it means the option of some negative α's won't be ignored. We introduce the set of signs of α_q, $s_q = \{\pm 1\}, q = 2, ..., k-1$ such that $s_q = s_{k+1-q}$. Then we get the solutions in the following general form

$$\begin{aligned} a_q(x) &= \left(\prod_{j=2}^{q} s_j \right)^{q-1} \left(\frac{x}{\sqrt{\alpha^2 - 1}} \right)^{\sum_{j=1}^{q-1} r_j} \frac{(x^{r_q} - 1)}{\alpha}, \; q = 2, ..., k-1, && (11) \\ a_k(x) &= \left(\prod_{j=2}^{k-1} s_j \right)^{k-2} \left(\frac{x}{\sqrt{\alpha^2 - 1}} \right)^{\sum_{j=1}^{k-2} r_j} \frac{x(x-1)}{\alpha^2 - 1 - x} && (12) \end{aligned}$$

Note that an important artefact of the baxterization procedure in the case of the Fuss-Catalan algebras is a necessary additional requirement that all the parameters α_q of different copies of TL subalgebras should be equal (up to some signs). Here and below we denote α_1 as α - the only free parameter remaining after baxterization, which, we in principle permit to be negative. This possibility of negative α(s) will extend variety of possible physical regimes of our statistical models.

In [1] the solutions with $s_q = r_q = 1$ were called fundamental. All others differ from it either by less powers of x appearing in a_q, or alternating signs of a_q. Both type of changes compared to the fundamental solution should respect the symmetries of parameters r and (10). The fundamental solution can be written as

$$W_i(x) = 1_i + \sum_{q=1}^{k-1} \frac{x^{q-1}}{\left(\sqrt{\alpha^2-1}\right)^{q-1}} \frac{x-1}{\alpha} U_i^{(q)} + \frac{x^{k-1}}{\left(\sqrt{\alpha^2-1}\right)^{k-2}} \frac{x-1}{\alpha^2-1-x} U_i^{(k)} \tag{13}$$

All the solutions for Boltzmann weights (6) we got have two important properties: unitarity

$$W_i(x)W_i(1/x) = 1_i \tag{14}$$

and crossing symmetry:

$$\overline{W}_i(x_*^2/x) = \left(\frac{x_*}{x}\right)^{\sum_{j=1}^{k-2} r_j} \frac{x_*^2 - x}{x(x-1)} W_i(x) \tag{15}$$

which becomes

$$\overline{W}_i(x_*^2/x) = \left(\frac{x_*}{x}\right)^{k-2} \frac{x_*^2 - x}{x(x-1)} W_i(x) \tag{16}$$

for the fundamental models. Here $x_* = \sqrt{\alpha^2-1}$, the "bar" operation means $\overline{U}_i^{(q)} = U_i^{(k-q)}, q = 1, ..., k, (U_i^{(0)} \equiv 1_i)$. In pictorial representation "bar" means rotation of TL generators by 90 degrees, as in the crossing relation of Boltzmann weights of a lattice models. These two symmetries (14),(15) are very important and play crucial role in derivation of inversion relation. Here and below we mainly stop on few representative examples of the plenty solutions described by (11),(12),(13). We will analyze in details $k = 2, 3, 4$, considering possible regimes of the models.

2.2 Examples and regimes

Here we write down explicitly all the solutions found for $k = 2, 3, 4$. Two color case has only fundamental solution

$$W_i^{(2)}(x) = 1_i + \frac{x-1}{\alpha} U_i^{(1)} + \frac{x(x-1)}{\alpha^2-1-x} U_i^{(2)} \tag{17}$$

In the case of three colors there are two possibilities

$$W_i^{(3\pm)}(x) = 1_i + \frac{x-1}{\alpha} U_i^{(1)} \pm \frac{x(x-1)}{\alpha\sqrt{\alpha^2-1}} U_i^{(2)} \pm \frac{x^2(x-1)}{\sqrt{\alpha^2-1}\,(\alpha^2-1-x)} U_i^{(3)} \tag{18}$$

where the case of upper signs (3+) corresponds to what we called the fundamental solution. There are more possibilities in the case of four colors. It is the minimal number of colors when what we called an excited solution (some $r_q = -1$) exists. Two solutions are

$$\begin{aligned} W_i^{(4\pm)}(x) &= 1_i + \frac{x-1}{\alpha} U_i^{(1)} \pm \frac{x(x-1)}{\alpha\sqrt{\alpha^2-1}} U_i^{(2)} + \frac{x^2(x-1)}{\alpha\,(\alpha^2-1)} U_i^{(3)} + \\ &\quad + \frac{x^3(x-1)}{(\alpha^2-1)\,(\alpha^2-1-x)} U_i^{(4)} \end{aligned} \qquad (19)$$

The fundamental solution is (4+) and (4−) is an excited one. There are more four color excited solutions:

$$\begin{aligned} W_i^{(4'\pm)}(x) &= 1_i + \frac{x-1}{\alpha} U_i^{(1)} \pm \frac{x-1}{\alpha} U_i^{(2)} + \frac{x-1}{\alpha} U_i^{(3)} + \\ &\quad + \frac{x(x-1)}{(\alpha^2-1-x)} U_i^{(4)} \end{aligned} \qquad (20)$$

If we now impose positivity of all Boltzmann weights, we can find different regimes of the models. It is convenient to give names to the following regions on the plain (α, x):

$$\begin{aligned} I &: \quad 1 < x < \alpha^2 - 1, \sqrt{2} < \alpha, \qquad (21) \\ II &: \quad \alpha^2 - 1 < x < 1, -\sqrt{2} < \alpha < -1, \\ III &: \quad 0 < x < 1, -1 < \alpha < 0, \\ IV &: \quad -\infty < x < -1, -\infty < \alpha < -1, \\ V &: \quad -\infty < x < \alpha^2 - 1, -1 < \alpha < 0, \end{aligned}$$

We will use the following parameterization of spectral and crossing parameters in the regions $I - V$:

$$I, II \; : \; x = e^u,\ \alpha^2 - 1 = e^\lambda,\ I:\ 0 < u < \lambda,\ II:\ \lambda < u < 0. \qquad (22)$$

$$III \; : \; x = e^u,\ \alpha^2 - 1 = -e^\lambda,\ \lambda < 0,\ u < 0 \qquad (23)$$

$$IV \; : \; x = -e^u,\ \alpha^2 - 1 = e^\lambda,\ 0 < u \qquad (24)$$

$$V \; : \; x = -e^u,\ \alpha^2 - 1 = -e^\lambda,\ \lambda < 0,\ \lambda < u \qquad (25)$$

Models "2" and "4′+" are physical (have positive Boltzmann weights) in all the regimes $I - V$. "3+" is physical in the regimes I and II, and "3−" – in the regimes IV, V. "4+" has all Boltzmann weights positive only in the regime I, whereas models "4−" and "4′−" are never physical in the sense of all Boltzmann weights positivity.

We see a rich spectrum of possibilities for different regions of parameters defining a positive Boltzmann weights. Only detailed investigation of the models can answer on the question what is the phase structure of the models and its relation to the regimes.

2.3 Vertex and IRF representations.

In principle it would be plausible to proceed with exact solution of these new integrable lattice models directly in terms of Fuss-Catalan generators. Such possibility is shortly discussed in the Sect.5. Here and below we formulate integrable lattice models in terms of more concrete representations of the Fuss-Catalan algebra. In this context the useful fact [2] is that the Fuss-Catalan algebra (1),(3),(4) is a subalgebra of tensor product of few copies of TL algebras with different parameters $TL(\alpha_1) \otimes ... \otimes TL(\alpha_k)$, and generators $U_i^{(q)}$ may be expressed in terms of $u_i^{(q)} \in TL(\alpha_q)$ as

$$U_i^{(q)} = \begin{cases} 1 \otimes ...1 \otimes u_i^{(k-q+1)} \otimes ... \otimes u_i^{(k)} & i - odd \\ u_i^{(1)} \otimes ... \otimes u_i^{(q)} \otimes 1 \otimes ..... \otimes 1 & i - even \end{cases} \tag{26}$$

Recall that one of the requirements of the baxterization procedure was the same value of $|\alpha_q|$ for different q.

The most studied lattice models are vertex models and interaction round the face (IRF) models. In the first case the TL operator $U_i^{(q)}$ acts on linear spaces attached to four links of square lattice connected to each site. Using a basis $\{e_i\}$ of the linear space the vertex Boltzmann weights W is defined as

$$W(x) e \otimes e = \sum_{i,j} W_{ij}^{kl}(x) e_i \otimes e_j \tag{27}$$

The fundamental representation for the usual TL generator u is known to be defined on a tensor product of two dimensional linear spaces in a matrix form:

$$1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \; u = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & z & 1 & 0 \\ 0 & 1 & 1/z & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \tag{28}$$

where z is related to the TL algebra parameter $\alpha = z + 1/z$. In view of (26) it is natural to define representation for the multicolored generator $U_i^{(q)}$ as the tensor product of matrices (28) (with, in principle, different parameters z) and identity matrices, as in (26). The linear spaces living on the links of the lattice are of dimension 2^k, where k is the number of colors.

Another representation of algebraically formulated lattice model Boltzmann weights $W_i(x)$ is an IRF representation. In this case some (integer) numbers are living at each site of the square lattice with a constraint that on two admissible (connected by a link) sites may appear only numbers permitted by some fixed admissibility graph. Then the representation is given (see e.g. [11]) on an elementary face of the lattice with site values (i, j, k, l) in the anti clockwise direction

$$1_{ij}^{lk} = \delta_{ik}, \; u_{ij}^{lk} = \frac{\sqrt{S_i S_k}}{S_j} \delta_{jl} \tag{29}$$

where S_i are components of the eigenvector of the admissibility matrix with the largest eigenvalue equal to the TL parameter α. $\alpha = 2\cos\frac{\pi}{m}, S_i = \sin\frac{\pi i}{m}$, with m-Coxeter number for models with ADE-like admissibility graphs, and $\alpha = 2$ for the extended $\widehat{A}\widehat{D}\widehat{E}$ admissibility graphs. Further construction of representation of $U_i^{(q)}$ generators goes by tensoring (29) according to (26). This tensor product of elementary IRF representations of TL operators will be defined on a tensor product admissibility graph. As we said above, not all admissibility graphs may participate in this tensor product, since their matrix eigenvalues are not arbitrary, but restricted by condition (10). Possible partners among ADE models which can be tensored, were classified in [1]. Actually there is even more freedom – one can make a tensor product of vertex and IRF models, consistently fitting their parameters α. But in what follows we will concentrate on two simplest examples – two color vertex model and two color A_n IRF models.

The simplest possibility for vertex realization is the model "2". In has 32 non zero Boltzmann weights and list of them one can find in [1]. Looking at this list, one can see that the model is not of ice type – there is no a natural "charge" conservation in each vertex. Linear space living on each of four edges of a vertex is four dimensional, such that R-matrix is 16 × 16. An interesting observation is that it is possible to attach "charge" to these four spaces in a way preserving "charge" conservation, but on a cost of charge degeneracy of the spaces. For instance, the attachment: space 0 → charge 0, space 1 → charge 1, space 2 → charge 1, space 3 → charge 3 – leads to "charge" conservation in each non zero vertex.

We formulate the model in the language of spin chain models, and consider the Boltzmann weights W as an L-operator. (Recall that R-matrix is related to L-operator by permutation P of outgoing spaces: $R = PL$, or $R_{ij}^{kl} = W_{ji}^{kl}$). We define the transfer matrix as

$$T_{o(e)}(x) = \left(W_{o(e)}(x)\right)_{c_N b_1}^{a_1 c_1} \left(W_{e(o)}(x)\right)_{c_1 b_2}^{a_2 c_2} \left(W_{o(e)}(x)\right)_{c_2 b_3}^{a_3 c3} ... \left(W_{e(o)}(x)\right)_{c_{N-1} b_N}^{a_{N-1} c_N} \tag{30}$$

There is a summation over repeated indices here, and indices o/e mean oddness(evenness) of the south site along the line of the auxiliary space c... As we see, T is an alternating product of Boltzmann weights on even and odd sites. (Recall that in the multicolored TL models they are different). In the language of spin chains Boltzmann weights may be considered as L-operators. Unitarity condition looks like

$$\left(W_{o(e)}(x)\right)_{cd}^{ab} \left(W_{o(e)}(x^{-1})\right)_{ef}^{cd} = \delta_e^a \delta_f^b \tag{31}$$

There is an important property of BW, which is a mixture of crossing (15),(16) and unitarity relation:

$$W_{o(e)}(x) = \frac{x(x-1)}{x_*^2 - x} M^{(1)} \left[W_{e(o)}(x_*^2/x)\right]^{t_2} M^{(1)} \tag{32}$$

Here t_2 means transpose in the second space of Boltzmann weights, corresponding to the auxiliary space of the transfer matrix. The matrix $M^{(1)}$ acts in the first space and has the form

$$M = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1/z & 0 \\ 0 & 1/z & 0 & 0 \\ 1/z^2 & 0 & 0 & 0 \end{pmatrix} \tag{33}$$

Another important symmetry is

$$\left(W_{o(e)}(x)\right)_{cd}^{ab} = P W_{e(o)}(x) P = \left(W_{e(o)}(x)\right)_{dc}^{ba} \tag{34}$$

The relations (31),(32) are almost enough for derivation of the inversion relation (see below).

As the simplest example of two color IRF models one can consider the case of tensor product admissibility graph $A_n \times A_n$. The general form of the RSOS Boltzmann weights are defined by (17),(26),(29)

$$\begin{aligned} W_{e(o)}\left(ii', jj', kk', ll'|x\right) &= \delta_{ik}\delta_{i'k'} + \frac{x-1}{\alpha} \left\{ \begin{array}{ll} \delta_{i'k'}\delta_{jl}\frac{\sqrt{S_i S_k}}{S_j} & \text{even site} \\ \delta_{ik}\delta_{j'l'}\frac{\sqrt{S_{i'} S_{k'}}}{S_{j'}} & \text{odd site} \end{array} \right. + \\ &+ \frac{x(x-1)}{\alpha^2 - 1 - x} \delta_{jl}\delta_{j'l'} \frac{\sqrt{S_i S_k S_{i'} S_{k'}}}{S_j S_{j'}} \end{aligned} \tag{35}$$

Pairs of variables $(i, i'), (j, j'), (k, k'), (l, l')$, siting at the south, east, north and west corners of a face, are any admissible set of integers in the range from 1 to n. Each of two quartets (i, j, k, l) and (i', j', k', l') are any permitted by A_n admissibility graph diagram independently,

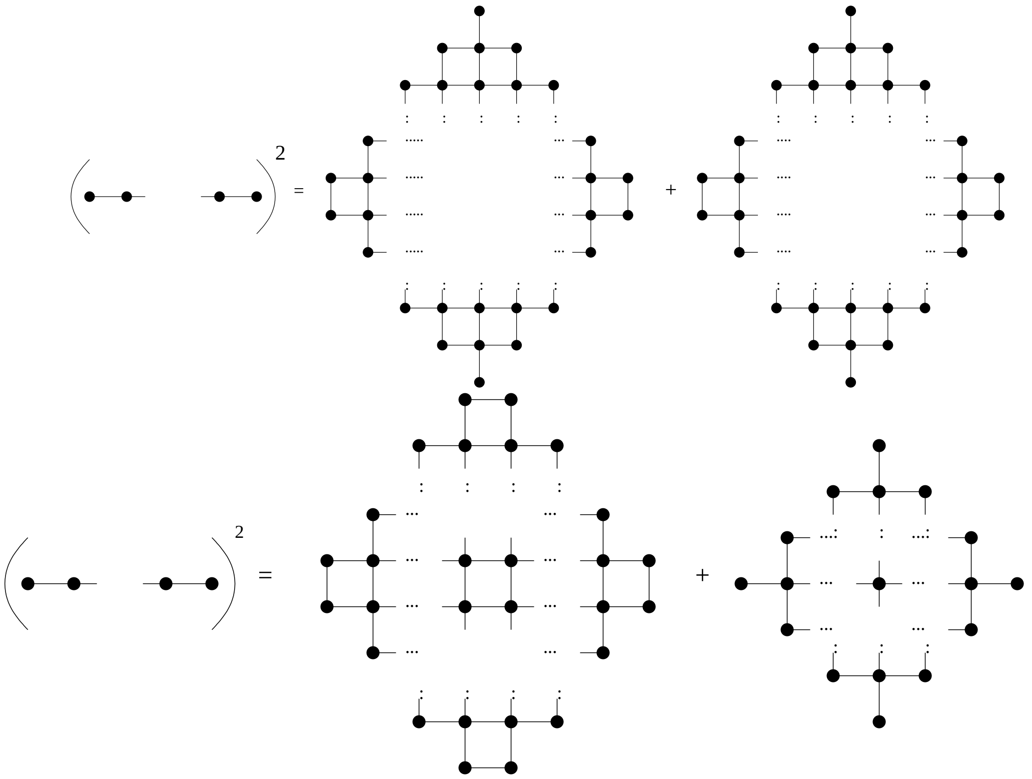

Figure 1: $(A_n)^2$ admissibility graph decomposition: **a** (upper) n is even, **b** (lower) n is odd

and $S_k = \sin\frac{\pi k}{n+1}, \alpha = 2\cos\frac{\pi}{n+1}$. One can explicitly check that these Boltzmann weights satisfy the following unitarity and crossing relations

$$\sum_{k,k'} W_{e(o)}\left(ii', jj', kk', ll'|x\right) W_{o(e)}\left(kk', jj', mm', ll'|1/x\right) = \delta_{im}\delta_{i'm'} \tag{36}$$

$$W_{e(o)}\left(ii', jj', kk', ll'|x_*^2/x\right) = \frac{\alpha^2 - 1 - x}{x(x-1)}\sqrt{\frac{S_j S_l S_{j'} S_{l'}}{S_i S_k S_{i'} S_{k'}}} W_{o(e)}\left(jj', kk', ll', ii'|x\right) \tag{37}$$

An interesting and important feature of the Boltzmann weights (35) is their admissibility graph decomposition property. One can check that admissibility rules coming from (35) lead to two independently existing subsets of site variables, each with its own admissibility graph. The form of these two graphs depends on oddness of n (see Fig.1a, Fig.1b).

Again, the basic object of investigation will be the transfer matrix

$$\begin{aligned} T_{o(e)}(x)^{\{\beta\beta'\}}_{\{\alpha\alpha'\}} \quad = \quad & \prod_{i=1}^{N/2} W_{o(e)}(\alpha_i\alpha'_i, \alpha_{i+1}\alpha'_{i+1}, \beta_{i+1}\beta'_{i+1}, \beta_i\beta'_i|x) \times \\ & W_{e(o)}(\alpha_{i+1}\alpha'_{i+1}, \alpha_{i+2}\alpha'_{i+2}, \beta_{i+2}\beta'_{i+2}, \beta_{i+1}\beta'_{i+1}|x) \end{aligned} \tag{38}$$

where the trace identification $\alpha_0 = \alpha_N, \alpha'_0 = \alpha'_N, \beta_0 = \beta_N, \beta'_0 = \beta'_N$ is imposed. Recall here an important and well known difference in definition of TM for vertex and IRF cases. In the vertex case the auxiliary space of TM contains a sum over thermodynamically many (N) variables c_i in (30), whereas the IRF TM does not contain any auxiliary space.

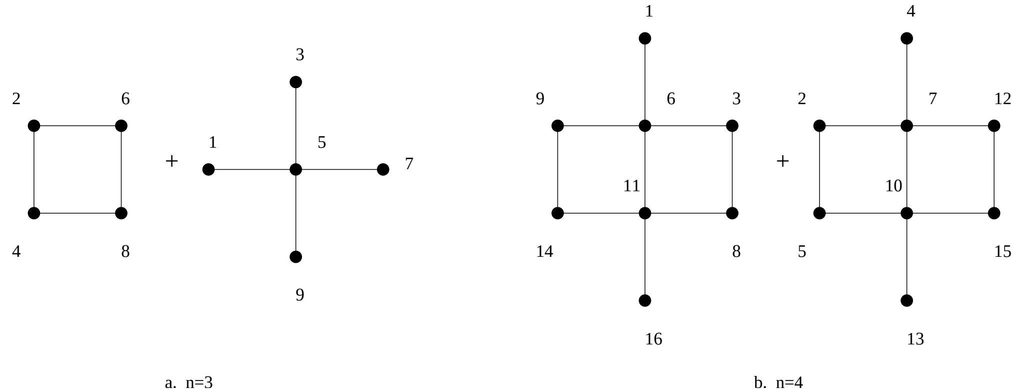

Figure 2: Admissibility graph decomposition for $(A_3)^2$ and $(A_4)^2$

Let us look in more details at the two color $(A_3)^2$ graph IRF model. This model, in a sense, may be called A_3"two color" Ising model, since, as it is well known (see e.g. [12]), A_3 graph IRF model is equivalent to the Ising model. Recall that A_3 admissibility rule requires that the height value is fixed and equal to 2 (the value of the middle site of A_3 graph) on the even sublattice of two dimensional square lattice, whereas the heights on the odd sublattice take the values 1 and 3, forming an Ising model. The situation is different in the two color case and the model seems to be more complicated then Ising model. As one can see by explicit analysis of non zero Boltzmann weights for the case $n = 3$, the RSOS model splits into two subsets of variables living on the sites of a face. If one denotes $(\{\overline{\alpha}\})$ the pairs of two numbers at the sites of a face as

$$(ij) \equiv \overline{\alpha} = 3(i-1) + j \tag{39}$$

the decomposition of the admissibility graph into two ones looks like it is shown on the Fig.2. It means that there are either even or odd heights in the new notation, living on each site of the model. It means the model factorizes into two separate submodels.

In the same way, admissibility graph of the two color $(A_4)^2$ graph IRF model, after the recounting of the site variables

$$(ij) \equiv \overline{\alpha} = 4(i-1) + j \tag{40}$$

decomposes into two disconnected graphs (see Fig.4a,b), dividing the model into two submodels – one with the site variables $\overline{\alpha} = \{1, 3, 6, 8, 9, 11, 14, 16\}$, another – with $\overline{\alpha} = \{2, 4, 5, 7, 10, 12, 13, 15\}$. Again there are two separate submodels.

Note that the relations (37) are valid for each of two submodels of $(A_n)^2$ admissibility graph decomposition.

3 Inversion functional relations and their solutions.

The most full and contemporary investigation of the models described in the previous section should probably follow the standard methods of algebraic Bethe ansatz. Unfortunately the obstructions we met on this way didn't allow us to proceed in this direction, and algebraic Bethe ansatz for these models remains an open problem. But some information about ground state energy and free energy, spectrum of low lying excitations, and even about some correlation functions, can be extracted using a method known for a long time [7], which doesn't require a knowledge of explicit form BA equations and transfer matrix eigenvalues. It is a method of inversion functional relations on the transfer matrix eigenvalues, which was successfully applied to few integrable lattice models [10]. It would be interesting to develop a universal algebraic method of derivation of inversion relations in terms of multicolored TL algebra generators, as it was partly done in [13] for usual TL algebra models, but in what follows we are going to consider the inversion relation in vertex and IRF representations of multicolored TL algebra, which we discussed in the previous section.

3.1 Vertex model

We start from the vertex model. Consider the product

$$(M)^{\otimes N}\, T_o(x_*^2 x)\, (M)^{\otimes N}\, T_e(x) \tag{41}$$

Since transfer matrices commute, their eigenvalues will satisfy the same functional relations as transfer matrices themselves. The above expression explicitly looks as

$$Tr_A Tr_B \Big[M^{C_1} W^{t_A}_{oAC_1}(x_*^2 x) M^{C_1} M^{C_2} W^{t_A}_{eAC_2}(x_*^2 x) M^{C_2} ... * \\ W_{eBC_1}(x) W_{oBC_2}(x) ...]$$

Insertion of the equal to 1 factor $(\delta_{a_i b_i} + 1 - \delta_{a_i b_i})$ in any place of this product leads to a split of the above expression into two terms – the first corresponding to the $\delta_{a_i b_i}$, and the second – to $(1 - \delta_{a_i b_i})$. Due to the relations (32),(31) the first term turns out to be proportional to the identity operator in all the C_i spaces. Oppositely, the second term is not giving an identity operator in any of C_i spaces. According to (32), the proportionality coefficient for the first term will be $\frac{1}{z^{2N}} \left(\frac{x_*^2 - x^{-1}}{x^{-1}(x^{-1}-1)} \right)^N$. One can show that the expansion of the second term in powers of x starts from the $x^{N/2}$, therefore in the region where $x > 1$, e.g. in the regime I, the second term is exponentially small compared to the first term in the thermodynamic limit. This leads to the following inversion relation

$$(M)^{\otimes N}\, T_o(x_*^2 x)\, (M)^{\otimes N}\, T_e(x) = \frac{1}{z^{2N}} \left(\frac{x_*^2 - x^{-1}}{x^{-1}(x^{-1} - 1)} \right)^N I_{C_1} \otimes I_{C_2} \otimes .....I_{C_N} + O(e^{-N}) \tag{42}$$

One can also see that specific of the matrix M is such that the relation between highest eigenvalue of $(M)^{\otimes N}\, T_o(x_*^2 x)\, (M)^{\otimes N}$ and of $T_o(x_*^2 x)$ is by factor $\frac{1}{z^{2N}}$. It leads to the following functional relation for eigenvalues of transfer matrix in the thermodynamic limit $N \to \infty$, when the terms $O(e^{-N})$ can be neglected

$$\Lambda(x_*^2 x) \Lambda(x) = \left(\frac{x_*^2 - x^{-1}}{x^{-1}(x^{-1} - 1)} \right)^N \tag{43}$$

Another relation is the unitarity relation. If one considers the product

$$T_o(x) T_e(1/x) = Tr_A Tr_B [W_{oAC_1}(x) W_{eAC_2}(x) ... W_{eBC_1}(1/x) W_{oBC_2}(1/x) ...] \tag{44}$$

then by insertion of the space permutation operator P ($P^2 = 1$) between the Boltzmann weights of, say, the second TM, and using (34), one gets

$$\sum_{\{a\},\{b\},\{c\}} W_o(x)^{d_1 a_1}_{a_N c_1} W_e(x)^{d_2 a_2}_{a_1 c_2} ... W_o(1/x)^{b_1 c_1}_{e_1 b_N} W_e(1/x)^{b_2 c_2}_{e_2 b_1} ... \tag{45}$$

If one inserts one delta symbol $\delta_{e_{i+1}a_i}$ for some i, then due to the relation (31) all the product will be reduces to the identity operator $Id = \delta_{e_1 d_1} ... \delta_{e_N d_N}$. One can also show that other terms successfully cancel. This leads to the second functional relation on the transfer matrix eigenvalues

$$\Lambda(x)\Lambda(1/x) = 1 \tag{46}$$

The functional equations (43),(46) can be solved by standard methods. These equations in the parameterization (22) for regime I, can be written in terms of $\overline{\Lambda}(u) = \Lambda^{1/N}(x)$, as

$$\begin{aligned} \overline{\Lambda}(u)\overline{\Lambda}(\lambda + u) &= \frac{e^{\lambda+u} - 1}{e^{-u} - 1} \\ \overline{\Lambda}(u)\overline{\Lambda}(-u) &= 1 \end{aligned} \tag{47}$$

In order to solve uniquely this system of functional equations, one needs additional information about analyticity of the function $\overline{\Lambda}(u)$. One can look for solutions in the form $\overline{\Lambda}(u) = F(u)f(u)$, where $F(u)$ is a general analytic non zero (ANZ) in the quadrant $0 < Re(u) < \lambda, 0 < Im(u) < 2\pi$ solution of the system

$$\begin{aligned} F(u)F(\lambda + u) &= \frac{e^{\lambda+u} - 1}{e^{-u} - 1} \\ F(u)F(-u) &= 1 \end{aligned} \tag{48}$$

and $f(u)$ is a solution of

$$\begin{aligned} f(u)f(u + \lambda) &= 1 \\ f(u)f(-u) &= 1 \end{aligned} \tag{49}$$

with a given set of poles u_p and zeros u_z in the same quadrant. We have cut the strip $0 < Im(u) < 2\pi$ in the imaginary direction because of the obvious $2\pi i$ periodicity of solutions of the system (47). The cut in the real axis direction $0 < Re(u) < \lambda$ is a consequence of the relation $f(u + 2\lambda) = f(u)$, which one can easily derive from (49).

The general ANZ solution of (48) has the form

$$F(u) = (e^u - 1)\prod_{j=0}^{\infty} \frac{\left(e^{(2j+1)\lambda+u} - 1\right)\left(e^{(2j+2)\lambda-u} - 1\right)}{\left(e^{2j\lambda+u} - 1\right)\left(e^{(2j+1)\lambda-u} - 1\right)} \tag{50}$$

For the double periodic function $f(u)$ we have the system of functional equations (49). Provided we know the set of its poles and zeros in the periodicity quadrant, the solution is uniquely fixed by Liouville's theorem:

$$f(u) = \pm \prod_{u_z} \sqrt{\kappa_1}snh\left(\frac{2K_1}{\pi}(u - u_z)\right) \prod_{u_p} \sqrt{\kappa_1}snh\left(\frac{2K_1}{\pi}(u - u_p - \lambda)\right) \tag{51}$$

where snh is a standard elliptic function with modulus κ_1 defined by the requirement that corresponding quarter periods K_1, K_1' are related by $\frac{K_1'}{K_1} = \frac{\lambda}{\pi}$. (50) and (51) give general form of transfer matrix highest eigenvalue as a function of spectral parameter u, provided one knows positions of its poles and zeros in the periodicity region. Obviously transfer matrix eigenvalues do not have poles in the physical region. Some numerics we did for the lattices of small size in regime I support the conjecture that the ground state eigenvalue do not have also zeros in the periodicity region, and $f(u) = 1$ for the ground state. Using (50) one can calculate the ground state energy of the model

$$E_0 = -\frac{d}{du}\left(\ln\overline{\Lambda}(u)\right)_{u=0} = -\sum_{j=0}^{\infty}\frac{\sinh\frac{\lambda}{2}}{\sinh(j+1)\lambda\sinh(j+\frac{1}{2})\lambda} \tag{52}$$

3.2 IRF model

Discussing the family of IRF models, we will concentrate on two color $(A_n)^2$ models. In the same way, the product of two transfer matrices (38) for the IRF model has the form

$$\begin{aligned} T_o(x_*^2 x)T_e(x) &= \sum_{\{\overline{\alpha}_i\}}\prod_{i=1}^{N/2} W_o(\overline{\alpha}_i,\overline{\alpha}_{i+1},\overline{\beta}_{i+1},\overline{\beta}_i|x_*^2 x)W_e(\overline{\alpha}_{i+1},\overline{\alpha}_{i+2},\overline{\beta}_{i+2},\overline{\beta}_{i+1}|x_*^2 x) * \\ & \quad W_e(\overline{\gamma}_i,\overline{\gamma}_{i+1},\overline{\alpha}_{i+1},\overline{\alpha}_i|x)W_o(\overline{\gamma}_{i+1},\overline{\gamma}_{i+2},\overline{\alpha}_{i+2},\overline{\alpha}_{i+1}|x) \end{aligned}$$

Using crossing and unitarity properties (37) of the BW one can easily see that insertion of one Kronecker $\delta_{\overline{\alpha}_i\overline{\gamma}_i}$ for some one i into the last expression, reduces it to the identity operator for all i with the prefactor $\left(\frac{x_*^2-x^{-1}}{x^{-1}(x^{-1}-1)}\right)^N$. It means that the identity element is in a sense "decoupled" from the others. With some effort, one can show that, like in the vertex case, x expansion of operators different from identity starts from x in the maximal power less then N. It leads to the same functional relation as (43).

$$T_o(x_*^2 x)T_e(x) = \left(\frac{x_*^2 - x^{-1}}{x^{-1}(x^{-1}-1)}\right)^N + O(e^{-N}) \tag{53}$$

Unfortunately in the IRF case the situation is different with the unitarity relation (46). Were we try to generate an identity operator for product of two transfer matrices $T_o(x)T_e(1/x)$, we would need to introduce $2N$ delta symbols in order to make the relation (36) working, without involving the crossing relation (37). (Recall that there is no any auxiliary space trace in the definition of the IRF transfer matrix). Apparently such drastic deformation operator cannot be negligibly small in the thermodynamic limit $N \to \infty$. There is the well known way to avoid this obstacle: one can pass to the bigger object – partition function.

Consider partition function for $2N \times 2M$ square lattice. It can be written in different ways

$$Z(x) = \sum_{p.b.c.}\left(T_o^{(N)}(x)T_e^{(N)}(x)\right)^{2M} = \sum_{p.b.c.}\left(T_o^{(M)}(x)T_e^{(M)}(x)\right)^{2N}$$

where the transfer matrix product means summation over the repeating site variables of the multiplied transfer matrices, and $\sum_{p.b.c.}$ summation over periodic boundary conditions in both directions. One can introduce a set g_{M+N} of delta symbols matching the boundary configurations for both statistical sums (see the dashed lines on the illustrating Fig.3 left). Insertion of the identity operator in the form $1 = g_{M+N} + (1 - g_{M+N})$ separates the partition functions product into two pieces:

$$Z(1/x)Z(x) = \sum\left(T_o^{(M)}(1/x)T_e^{(M)}(1/x)\right)^{2N} g_{M+N}\left(T_o^{(N)}(x)T_e^{(N)}(x)\right)^{2M} + O(x) \tag{54}$$

One can see that the first term "collapses" into operator identifying configurations on all the sites of both lattices due to the relation (36). This "collapse" goes plaquette by plaquette, without

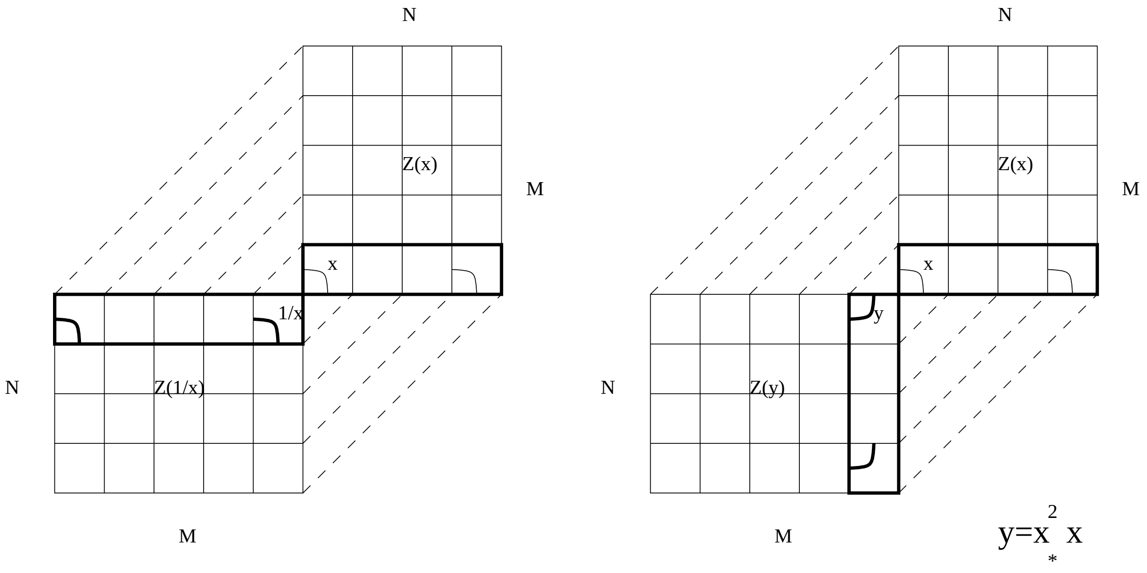

Figure 3: Illustration of inversion relation derivation for IRF model

any relation to the transfer matrices. The second term $O(x)$ represents deviations from identity. Here we will *assume* that the boundary changing operator g_{M+N} produces only subdominant terms for partition function. This assumption was shown to be correct for some IRF models [10], but investigation of this question is needed in the case of our IRF models. With this assumption the first term in (54) is dominating over $O(x)$.

In the similar way one can translate the relation (53) valid by itself, to the language of the partition functions product. One can see (for illustration see the Fig.3 right) that the same g_{M+N} does the job:

$$Z(x_*^2 x)Z(x) = \sum \left(T_o^{(N)}(x_*^2 x)T_e^{(N)}(x_*^2 x)\right)^{2M} g_{M+N} \left(T_o^{(N)}(x)T_e^{(N)}(x)\right)^{2M} + O(x) \tag{55}$$

In the first term, as it is illustrated on the Fig.3b, the product of the right column transfer matrix of $Z(x_*^2 x)$ with the lowest row transfer matrix of $Z(x)$ by (53) is proportional to the identity operator. This "collapse" to the identity continues to the product of the next to right column with the next to lowest row, and so on. By the same reasons as in the previous (54) relation, one can believe that the first term is dominating in the thermodynamic limit.

The dominating terms of equations (54),(55) lead to the system of functional equations for partition function density $z(x) = Z(x)^{1/MN}$

$$\begin{aligned} z(x)z(1/x) &= 1 \\ z(x_*^2 x)z(z) &= \frac{x_*^2 - x^{-1}}{x^{-1}(x^{-1}-1)} \end{aligned} \tag{56}$$

which coincides with the equations (47) in the proper regime parameterization. Numerical simulations show that for two color $(A_3)^2$ and $(A_4)^2$ models $z(u)$ is ANZ in the periodicity domain. It means that the solution for partition function in the ground state $z(u)$ is given by (50). An interesting property of it is that $z(0) = 1$.

3.3 Spectrum of low lying excitations

In the same way one can consider the low lying excitations, i.e. those states for which the transfer matrix eigenvalue $\Lambda(u)$ is finitely different from the ground state one $\Lambda_{gs}(u)$ in the thermodynamic limit. For instance, define finite function

$$l(u) = \lim_{N\to\infty} \frac{\Lambda(u)}{\Lambda_{gs}(u)} \tag{57}$$

for vertex model. Again $l(u)$ can be represented as a product of ANZ function $F(u)$ and another one $f(u)$ satisfying the same functional equations (48),(49). But this time $f(u) \neq 1$, and some zero(s) u_z enter into the periodicity domain. The excitation spectrum can be calculated from the relation between energy and momentum of excitations

$$\begin{aligned} E - E_0 &= -\sum_{\{u_z\}} \frac{d}{du}(\ln \psi(u))_{u=0} = \sum_{\{u_z\}} \varepsilon(p(u_z)) \\ P - P_0 &= -i \sum_{\{u_z\}} \ln \psi(0) = \sum_{\{u_z\}} p(u_z) \end{aligned}$$

where $\ln \psi(u)$ is the contribution of each *snh* factor in the product (51). Using (51) we get the dispersion relation:

$$\varepsilon(p) = K' \sqrt{(1-\kappa)^2 + 4\kappa \sin^2 p} \tag{58}$$

with non zero mass gap

$$\Delta = K'(1-\kappa) \tag{59}$$

So, at least in the regime I, where one can neglect the additional terms in the inversion relation, all the excitations are with a non zero energy gap. It means there is no conformal critical point in this regime.

Importance of the regime in all what was done above, is crucial in two aspects. First, in order to neglect the non identity terms in the inversion relation one needs $|x| > 1$, which is correct not only for regime I, but also for regime IV and $x < -1$ subregion of the regime V (we will call it V'). Second, the numerics, which is necessary to be sure in ANZ condition, essentially differ for different regimes. The analog of (47) for vertex model in a parameterization (24),(25) of the regimes IV, V' looks like

$$\begin{aligned} \overline{\Lambda}(u)\overline{\Lambda}(\lambda + u) &= \frac{e^{\lambda+u} - p}{e^{-u} + 1} \\ \overline{\Lambda}(u)\overline{\Lambda}(-u) &= 1 \end{aligned} \tag{60}$$

where in the regime IV $p = -1$, and in the regime V' $p = 1$. Equation (49) remains as it is. It means the solution for F in this case is given by

$$F(u) = (e^u + 1) \prod_{j=0}^{\infty} \frac{\left(e^{(2j+1)\lambda+u} - p\right)\left(e^{(2j+2)\lambda-u} + 1\right)}{\left(e^{2j\lambda+u} + 1\right)\left(e^{(2j+1)\lambda-u} - p\right)} \tag{61}$$

$f(u)$ is given by the same solution (51). With the assumption of ANZ condition for $\Lambda(u)$ it leads to the following ground state energies of the two color vertex model in the regimes IV and V':

$$E_0^{IV} = -\sum_{j=0}^{\infty} \frac{\cosh\frac{\lambda}{2}}{\cosh(j+1)\lambda \cosh(j+\frac{1}{2})\lambda}, \quad E_0^{V'} = -\sum_{j=0}^{\infty} \frac{\cosh\frac{\lambda}{2}}{\cosh(j+1)\lambda \sinh(j+\frac{1}{2})\lambda} \tag{62}$$

The analysis of low lying excitations remains the same, giving the same finite energy gap (59).

In the same way one can modify the solutions for partition function $z(u)$ of two color IRF models in regimes IV and V'. With an ANZ hypothesis, it is given by the same expression (61) with the same property $z(0) = 1$.

4 Other models.

A natural conjecture is that all what was done in the previous section for two colored models, can be generalized for what was called above fundamental models with any number of colors in the regime analogous to regime I. Lets point out that both three and four colored models have only regimes I and II as regimes with all Boltzmann weights positive. As we said, $x > 1$ only in the regime I, which was crucial for derivation of inversion relation. Instead of (32) we have

$$L_i(x) = \left(\frac{x_*}{x}\right)^{k-2} \frac{x(x-1)}{x_*^2 - x} \widetilde{M}^{(1)} \left[L_{i+1}(x_*^2/x)\right]^{t_2} \widetilde{M}^{(1)} \tag{63}$$

with some matrix $\widetilde{M}$ acting in the first space. Together with (31) it gives the following inversion relations

$$\begin{aligned} T(x)T(x_*^2 x) &= (x_* x)^{k-2} \left[\frac{x_* - x^{-1}}{x^{-1}(x^{-1}-1)}\right]^N Id + O(e^{-N}) \\ T(x)T(1/x) &= Id \end{aligned}$$

As we see, they differ from (53) is minimal way – by a prefactor. The same procedure as previously gives

$$\begin{aligned} \Lambda(u) &= \overline{\Lambda}(u) f(u) \\ \overline{\Lambda}(u) &= e^{(k-2)u} (e^u - 1) \prod_{j=0}^{\infty} \frac{\left(e^{(2j+1)\lambda+u} - 1\right)\left(e^{(2j+2)\lambda-u} - 1\right)}{\left(e^{2j\lambda+u} - 1\right)\left(e^{(2j+1)\lambda-u} - 1\right)} \end{aligned}$$

with the same expression (51) for $f(u)$. It leads to integer shift of the ground state energy in $k-2$, compared to (52), provided still $f = 1$ (ANZ hypothesis). This of course should be checked numerically.

Looking at the other models which have some physical regimes, one can believe that the general form of inversion relations both for fundamental models with some negative signs and for excited models with or without negative signs, is just

$$\begin{aligned} T(x)T(x_*^2 x) &= (x_* x)^{\sum r_j - 2} \left[\frac{x_* - x^{-1}}{x^{-1}(x^{-1}-1)}\right]^N Id + O(e^{-N}) \\ T(x)T(1/x) &= Id \end{aligned}$$

Form of solution of these equations depends on regime. We see that different models have the same set of functional inversion relations, and sometimes even the same set of regimes.

One can believe that if there is a difference in ground state or low lying excited states between these models, then it is expressed in the amount and location of poles and zeros of function $f(u)$. An information about these poles and zeros may come from numerics.

5 Discussion

In this paper we made an attempt to analyze vertex and IRF multicolored lattice models. We saw an interesting structure of admissibility graph for IRF models. Being unable to solve the models by algebraic Bethe ansatz, we tried to analyze them using the inversion relations. The main result of this attempt - all the models have a mass gap in the considered regime. Another evidence for absence of conformal points in this regime we saw formally trying to construct new link invariants, following a standard procedure of extracting a braid group representation from the Boltzmann weights either in vertex or in IRF form (see [14] and references therein). The objection we met in this way is that it is impossible to get a well defined braid group representation taking a limit $u \to i\infty$, or some other one, for the two color Boltzmann weights $W(u)$. Also the formal sufficient condition for construction of link invariants from $W(u)$ one can find in [14] is not satisfied. But one cannot reject a possibility of gapless behavior for the models we considered in other regimes, as it was pointed out in [6] for dimerised coupled spin chain.

Let us stress an almost unrestricted amount of possibilities in construction of new integrable multicolored TL models demonstrated above. Certainly these zoo of new models deserves a classification which, as far as we know, is missing for today.

An interesting possible alternative is coordinate Bethe ansatz formulated in terms of the Fuss-Catalan algebra itself. Such kind of Bethe ansatz formulation, purely in terms of usual TL algebra generators for the XXZ model, was applied in [15]. The basis for wave function representation was chosen as a basis of specially defined two sided ideals of words of TL generators. It would be interesting to apply such formulation to the multicolored TL lattice models.

This paper is only a first touch to these new integrable models. Development and applications of known methods of integrable models, such as algebraical Bethe ansatz, transfer matrix functional relations leading to a (system of) integral equations, a role of Q-operator in these models, and so on – are open and interesting problems.
